

[fw-wiz] General guideline for embryonic vs. max connections?

Hi,

I'm configuring a new pix 515e and I'm wondering if there is a rule of thumb for setting the ratio of embryonic vs. max. conn's in a (static) translation rule? In other words given a max. conn. value of 500, could you expect roughly 5% of that number to be in an embryonic state at any given time?

I realize that this would vary greatly depending on the type of server, time of day, etc – but I'm just looking for a starting point.

Any thoughts on configuring these two values would be appreciated.

Regards,
Nick
