Key management – What it would take to setup key management and who would maintain the keys? What both free and Vendor solutions (SSH LTD and F-Secure) exist for Key management? If we don't implement with key management, how can we still be as secure? In other words for user/server authentication are there other models that work as well? <= I have related back that servers have two ways to authenticate (certificate and keys) and users have @7 ways (passwords, certificate, keys, PAM, etc) but I was going to dig up more on that as well.

Any ideas and help appreciated
