I am in QA attempting to test our SW's connectivity from server to client. We are supporting SSH1 and SSH2 as configurable options. According to one of our developers, if the user selects SSH1 and the client is using an SSH2 server, SSH1 will still be supported as well in order to achieve backward compatibility. However, the server is NOT able to connect to the client and the message I receive is that the server does not support SSH1. Sorry if this doesn't make sense, I am new to SSH. I would appreciate any positive insight into the issue.
