Maybe I'm wrong.

I don't see that capability in my SMC routers either (I've three at various locations), but they're all somewhat aged at this point (two are ..11b).

The "virtual server" component – which is what does this type of port forwarding – has the first three triples of the IP of the destination of the forwarding "hardcoded" to the class C on the LAN side.

[And this makes me realize how stupid these boxes really are...assuming that the LAN side must be a /24?]

Perhaps newer devices are smarter and more flexible?
