I was reading an article on sanitizing user input on forms and decided to do an audit of my application over the holiday. I found a variety of problems, which I repaired. It appears as though none of these problems were ever taken advantage of, thank goodness.

What I thought would be interesting to this group is that one place where I found a potential `cross site scripting` bug was some code I had copied from the Ibuyspy portal sample program. I had copied the `good reads` control to add a music review section to my site. In the title input parser, I added a Server.HtmlEncode call that wasn't there in the original code from Ibuyspy while doing my audit.

I do not know how to check to see if this is truly a problem, I am a beginner with this security stuff. Can someone who knows better tell me how to test this?
