Will look into this. Thanks again Scott.

Take cares.

J

It is a good idea to separate the connectionstring from the program code by putting it into a config file, yes. Then, your program can extract the info. from that file as needed. I haven't used the login control, but I'm sure you can add code to the page\_load event handler to programmatically set this up.

Good luck.

So would one make this adjustment in the web.config file? Also would this still be able to use and work with dragging and dropping the Login control objects onto the web form?

Thanks a bunch Scott for your info and quick reply. I appreciate it.

Hello. Sorry if this is a novice question but can anyone show or point me to some code in having windows authentication to sql server for an asp.net application where it's not using just one generic windows account? I need to assign individual windows logins to our users (basic authentication in conjunction with https since not everyone is on the same domain). I notice in pretty much all the examples/samples I see on the net they have the asp.net apps use 1 generic or surrogate windows connection to sql server that's on the same domain but how does one configure the asp.net app to allow individual windows authentication for users to access the asp.net app from anywhere on the web? The reason I'm asking is because I need to use SQL Profiler in seeing who did what to the data at what time, etc...

Thanks in advance.

J
