he never mentioned he is impersonating in asp.net – so no delegation needed. Cassini runs with the credentials of the interactive user – which seems to have access to sql – in contrast to the local ASPNET account – which i am trying to tell him since 2 days....

yes – use explicit credentials and enable mixed mode auth in sql server to get this to work.

I assume when you used filesystem, you had IE running on the same box as the web server so there was just a single hop for authentication and thus delegation was not needed. I also assume filesystem runs with your credentials – not ASPUSER but I'm not an expert on ASP.Net. Your problem could be either ASPUSER not having permissions or delegation. The easiest solution for either one is to setup a SQL Server authenticated login and try connecting by putting the user name and password in the connection string. If that works you at least know what the problem is and can try to address it.

I tried creating a website with FILE SYSTEM, not HTTP, and I was able to open the web page in IE with SQL server data. ASPUSER is used for connecting to the SQL SERVER machine with FILE SYSTEM web site ?
