Hi, I'm using vs2005, .net2 for a windows applicaiton. I need to bind to an AD object (user, group or computer) and I only have its sid. This object could locate in a domain outside of my current forest, in a multi-forests environment.

1. How can I find the path to this object?
2. How to find the domain name that this object is located.
3. If this object is not in current forest, then, how can I verify if the forest/domain that this object is at has a valid external trust configured with my current forest?

Any help in any of the above issue is greatly appreciated.

Thank you.
