Response:

This is a work group environment. Namely there is no a central security database as it is in a domain environment. Computers in the same workgroup will be visible to one another. Still "each" machine has its own security database locally. Consequently each machine will need to have the account information of an intended user. Also in IIS console, rightclick the web site and go to properties/directory security/edit anonymous access and authentication control, uncheck Integrated Windows and check Basic authentication. This will allow user credentials to be passed to IIS for authentication. More information on how IIS authenticates a user, please review

Q308160 HOW TO: Configure Internet Information Services Web Authentication in
