This is the setup

1. Goto a web site (IIS) and you are prompted for a domain password.
2. Once logged in you can browse the site...until you go to a asp page that calls information from another server that has SQL Enterprise on it.
3. When you access a asp page from the website – it communicates with the SQL server which is setup with domain authentication – The SQL server requests a user id and password (doamin login and password) but since the asp page is running on the IIS webserver it sends the anonymous account information to the sql server not the login information from the user.
4. Does the ASP page need to aquire the user login information and send that to the sql server

or

Is there a setting in IIS to pass the user login information to the SQL server.

thanks
