Hi,

I posted this to the microsoft.public.inetserver.iis group, but then found this one and thought it might be a more appropriate place.

here's the problem. It's fairly long.....and it is seriously starting to annoy me too! :-)

IIS5 – Windows 2000 Server

I've created a new website called Systems Team. It's running on port 80, same port as the default site, so I've given it a host header of systems.test.co.uk. The bit after systems is our domain name.

I've created a DNS entry in our test.co.uk zone called Systems pointing to the IP of the server.

No problems so far. All website access is fine using a URL of <http://systems.test.co.uk>.

Now, when I restrict permissions on the folder that the website maps to it all goes pear shaped. I have permissions set so that only Domain Admins have rights to the folder. The website is configured for Integrated Authentication and Basic Authentication. Basic is so that we can access it if we're not logged into a PC as ourselves.

Now when I go to systems.test.co.uk, I get prompted for a username and password. If I enter my details which I'm already logged on with, I get in fine. So for some reason, the integrated authentication isn't working.

Now if I remove this new site, add a Virtual Directory under the default site, so I just reference the site by <http://servername/systems> I get in with no problems.

Soooo...it seems to be a problem with using Host Headers and permissions on the website folder.

microsoft.public.inetserver.iis.security: Host headers and integrated windows authentication problems

Anyone got any ideas?

Cheers,

Adam
