There are certain rights that administrators need to have – otherwise you can be in trouble when something goes wrong. If you want to give users less rights (only certain specific rights) you can easily create a NEW GROUP then you can assign whatever rights you want to that group and give whomever you want to this new group.

I recommend NOT to touch the Admin group's rights.

Administrators have take ownership privilege, so they can take ownership of any ACL they are denied access to and then change it.

I think you right.

But my idea was:

user rights are controlled using group policy, I think that group policy

is like front–end, and real control elements are registry

Re: Who can alter User rights ?

keys/values.

And every registry key has it's own permissions. So If I find registry

key which corresponds to particular user right, maybe I can allow more to

one administrative account than other(administrative) accounts using

registry permissions ?

It's my guess basically, but ?

thanks

Vilius
