

Setting Table Permissions?

This may be an obvious question, but I've noticed that there are three settings for setting table level permissions to a user/role: Unchecked, Checked, and X'd. What is the significance of having THREE states? It seems you would either grant or deny access. The default is unchecked – what does this state imply, granted, or not? Do I have to go through and mark everything with an X where I don't want user access, say for Update?

Much thanks,
Jason
