Correction: It looks like it is actually **working**.

I sniffed the packets with force encryption on and cannot see anything intelligible.

I sniffed the packets with force encryption off and I can make out everything passing back and forth between the sql server and the client.

What is wierd as far as I'm concerned is how this is supposed to secure the system if **anybody** can connect. Basically the only protection it gives you is preventing packets from being sniffed and read, so someone could **still** connect using SSL and run a dictionary attack trying to guess sa if they knew what port you were on.
