What is the best way to go to track changes by developers that are privy to db usernames and passwords?

Not all application users have domain accounts, so we can't use trusted connections. Instead, we have a single username that the application (we only have one) uses to perform its work.

We have auditing at the internal application level...Now we need a way to determine if any of the four developers are possibly manipulating data.

I briefly looked at application roles, but considering that you can run `sp_setapprole` from the QA, that doesn't seem worthwhile.

How is everyone else doing it? Our auditors assure us it is being done...

Don't you love SOX?

Thanks!

Joseph
