There may be a way through group policy to cause this. I was trying to determine if it might be the result of a user setting a timeout to lock the workstation. In a workgroup setting, they can be very difficult to deal with. Mostly they know just enough to cause everyone else problems. (I had one guy who browsed porn sites and went to great lengths to keep others from seeing his desktop. Others were just concerned that someone from another lab might see their data by accident.)
