Well I shutdown the entire Net and all attached devices, tried your suggestions but to no avail

I created a new wks and the station works as it should, but all my other wks and workgroup servers still can not change file/directory/share security of other network attached machines. Strange and lucky, I still have full file access. Have researched the web for hours on end and have not come accross anyone with the same problem; all references to similiar problems refer to domains. This affects 40 machines, and I do need to administer at least the servers remotely

Yes, I had at least one machine logged in with the old password when I changed the password on the machines in the workgroup. On the weekend I will bring the entire network down and change the password again, one machine at a time.*
