G/day forum,

we've got an FTP server on a DMZ, from this DMZ I've got clients coming in through VPN and I've got clients accessing Virtual Directory structure via mapped drives from our Corporate private network. Now this drive is authenticating using credentials which are local users on the FTP server. In the past few days I've had several users on our private network telling me that they could not access the relevant site through the mapped drive with these existing credentials. However, they could access this site using FTP. The only way to re-establish connectivity with this source was to disconnect the mapped drive and set it up again.

Can anyone let me know why this is happening??

Regards,
Steve.
