If you have not done so, add the users domain account to the local administrators account on their machine. If that does not work, then create a local user account that is a member of the local administrators group on their machine and have them log in with that account to the local machine to see if problems persist. It is possible that even if a user logs on to a machine as a domain member and has local administrative rights on that machine, they could still be subject to group policy user configuration [probably case with network properties restriction]. You can use gpresult [free download from MS] to find out where Group Policy configuration is coming from. --- Steve
