I can never seem to achieve a system recovery by any of the suggested means (e.g. Repair disk...) and the slightest irregularity

Amongst the startup variables causes for blue screens that persist and usually require hours upon hours of deductive work to get the thing going. In exchange for this reality the system is so much more stable than others: once it is up and running it should be left running until the entire machine dies.

Often I have had to reinstall which of course means everything else.

This time I will not do that, and almost achieved success but when the machine yesterday was revived it seemed to drop down a protectionary screen

Believe barring access to the 2 accounts on the machine (log on were messaged with "could not log you on (even admin acct- have logged you on as a default user. No or very few software operating system settings can be saved. I log On as admin and in the MMC dept. I cannot snap in the group policy item which must be where essentially the problem must be as would apply to default user permissions a lock out preventing any such environmental changes.

How can I get access, if not as Administrator to the Group policy or from another perspective is this the area that is preventing even drivers from being installed?
