Get a GPO defined and linked to your OU and write of its settings within that GPO delegated to you. The above is AD level 101. Those controlling the enterprise need to understand that and leverage what is Windows to enable you in your work. Feel free to forward the comment.

Otherwise, you could define a security template and then use `secedit` at each machine to import it into the local security policy. Regretfully, as you do not have access to startup script policies for the machines, you would have to do this by being innovative or by visiting 600 machines.

Now, you do not say what reg keys you were touching, but if they are ones with `/Policies/` in their path, and you are finding that your changes to values do not stick, then doing as just outlined for adjustment of local policy will yield no joy. That your manual changes do not stick shows that they are being controlled by AD based GPO policy settings.

Your solution is in getting the domain admins to delegate as the Windows architecture allows and intends.
