Patrick,

Restricted Groups work well, but be careful with these and test before you deploy widely. Remember that these will completely overwrite the local group rather than being additive.

You can use a Group Policy "startup" script using the net localgroup "localgroupname" "domaingroup" \add command in a batch file or use Restricted Groups. You could make the domain global group the restricted group and specify the localgroup in "this group is a member of" at the OU level with a GPO configured with restricted groups and add the computers to the OU that you want this to happen to. The link below explains more on G. --- Steve
