I would not think so for XP SP2 but you certainly can try it. I suggest that you also post in the Active_directory newsgroup to see if anyone there can help. The other thing you might try is to enable auditing of directory access for failure only [even if just temporarily] in Domain Controller Security Policy and then audit the root domain container and the container that contains the users for full control [if it does not inherit auditing from the domain container] for user objects only for everyone, anonymous, and self to see if anything is then found in the security logs of the domain controllers next time it happens.

Hi,

I checked and the Everyone group already has the access as detailed in those two MS articles. (Ability to change password on all user and computer objects). So no luck there.

Since EveryoneIncludesAnonymous is set to 0 (on the domain controllers) could that be what the problem is? Would I need to give "Anonymous Logon" the rights to change password to get around the need for setting EveryoneIncludesAnonymous to 1?

thanks again
