Hello,

I'd like to create a template of folders for the end users, including permissions. When we get a job, this new file structure is created including many many sub-folders.

Most of the sub-folders would be fine inheriting the permissions, but I have at least one sub-folder "Contracts" where one user gets full permission and the rest of the inherited people get read-only.

I'd don't know where to start looking, so I'm here. Any suggestions? If an answer is scripting, I am quite new to that area and may need a few examples or references. Also, I know coping folders only inherits permissions, moving folders also moves the permissions.

Windows 2003 Std w/AD
