Hello,

I have been advising people that should a company require separation in terms of security that a Forest is the only true boundary. However, Im now in a situation where a company who requires two of its business to be kept separate from each other, while maintaining a single global address list and calendar sharing...

My question is this, In one forest is it possible to secure it in such way that administrators in one child domain cannot interfere or put at risk other child domains with in the forest? taking into consideration removal of enterprise admins from the child domains and in the root domain service level administrators are trusted across the entire company.

Trusts between forests would not provide a solution in this due to the security constraints with in the company, Total separation means total separation. They have tasked me with pointing out what the exact security risks are, and whether they are manageable through design with in a single forest.

Any pointers / help on where to look for information or advise would be most gratefully received.

Many thanks

Paul,
