That is exactly the got ya here. AFAIK the limit is hard-wired and was set back when memory was much more limited and expensive, and when systems were single user machines. The issue is how many winstation desktops are there on your running system as it seems you may need to increase this (or to figure out why the app is consuming so much heap and adjust design so objects are released at earliest opportunity) but that increase in size of each impacts the total number of allocations you have available. I would be glad to find out there is a doc'd way to adjust this 48 meg size, but I have not run on that info.
