I have a VB6 app that uses MTS/COM+ for transaction processing surrounding SQL 2000 database updates (using ADO). The app was working fine on Windows 2000 Advanced Server until SP4 was applied to the server. Now the app fails on the first call to SQL Server inside the transaction context. The SQL Server instance is on the same server machine as the VB6 app.

I have verified that MSDTC is started.

I have added the domain administrator group to the Default Access Permissions in DCOMCNFG.

The DTCTester tool completes successfully
RPC port 135 is open

The application runs successfully on a Windows 2000 Server with SP4.

Is there something different about Windows 2000 Advanced Server SP4 vs. Windows 2000 Server SP4 or Windows 2000 Advanced Server w/out SP4?

Thank you.
