IIS 6.0 is fairly secure by default in that it is very locked down compared with previous versions and not enabled by default. The links below should help. General procedures such as a firewall, disabling unneeded services, using antivirus, strong passwords, log monitoring, and keeping current with critical security updates are also important steps. The free Microsoft Baseline Security Analyzer is also a great tool to check certain security vulnerabilities on your computer including for IIS as is the Security Configuration Wizard for SP1. --- Steve

Hi,

is there any good tutorial for a semi-newbie on how to set up IIS 6.0 on a windows 2003 server to make it as safe as possible?

I mean a step-by-step guide to follow that will make the webserver safe.

Thanks

/Surre
