I looked into xcacls.vbs, but am not sure that this will do what I want. Switch /R will revoke specified user's access rights, but not remove the user group. For example: my program will download file permission for a file on day 1. The user groups are "administrators", "system", "lg_processors", and "xnn8tty". On day 7 I perform the same download and now there are 5 user groups because "everyone" is now present besides the prior four. This is usually caused by the user checking the inherit from parent box on the advance permission tab. What I need to know is how to delete/remove "everyone" user group from that file using vb code and not set revoke permission or remove it using the remove button on the advanced tab. I thought about using /net command remove user, but I believe that will delete everyone from all files in my domain. Your help is greatly appreciated.

Check out xcacls.vbs which you can obtain from search on the filename (note: that is .vbs) at microsoft.com/downloads
This VBscript file examples pretty much any possible ACL manipulation. Also, you could look into fileacl from sourceforge.

I'm using subinacl.exe to download file permissions on a server. Then, we edit certain permissions once a week. However, I need to know how to

[quoted text clipped – 7 lines]

can
do the job?
