Then consider either don't give domain users/users/everyone/authenticated user permissions to any shares and instead give permissions to the global groups you want to have access or give the global group deny permissions to the shares you don't want them to access or deny access this computer from the network user right for computers you don't want them to access shares [other than domain controllers] on which can easily be managed via Group Policy. Every time a user is created for the domain that user is automatically added to the domain users group. --- Steve

Steven L Umbach wrote:

I do NOT recommend that you try to remove users from the domain users group as a strategy to manage access to shares or any other reason. Instead create global groups that contains the users that you want to have access to each share and then grant those global groups permissions to the shares and do not include users/domain users/everyone/authenticated users in the access control list for share permissions. -- Steve

Hi,

I have few shared folders on my w2k3 file server and most of them allow read access for the domain users group.

I am trying to create a shared folder that only allows one group of users to access. This group of users should has no access to

Re: removing user from domain users group doesn't help

other
shared folders. I created a new group and put all these users
onto the
group and removed the domain users group from the
"member of" property
of these users. So all these users are only member of the
newly created
group. However, they are still able to access the file on the
shares
that have read access for domain users.

Can someone advice how I can change the ntfs/share
permission so that I
achieve my goal accordingly?

Thanks

OM

If the users still belong to the domain user group, they would be able to
access to other shares that have access permission assigned to domain user
group within the domain. I just want them to be able to access one single
folder only. Thanks
