Clever. I like that and am going to remember that trick. I did not realize that access to a network share was denied if the user was not logged onto their list of allowed domain computers. I tried it also and got some obscure error message that would not tip the user off as to what was happening. Certainly not manageable in all but the smallest domains but if it works for their needs that is great. Yes I agree that a barrier for the average user is certainly worth pursuing. I assume most everybody locks their house and car doors even though that will not stop the determined criminal. After all I can just go on your roof and saw a hole in it to get in or simply tow your car away.

Thank you all for your input and ideas, and also the hint from Miha to the interesting KB article 822158

Have also found an interesting checklist at [http://searchwindowssecurity.techtarget.com/tip/1,289483,sid45\\_gci1024016.00.html](http://searchwindowssecurity.techtarget.com/tip/1,289483,sid45_gci1024016.00.html). There is an additional idea: Restrict User Logons to specific machines. Have tested this in a VM environment and it works as expected. A user with his private notebook can not attach to resources on the server with his user credentials. It's not very good security, because when the home user rename his private notebook to the same name than his corporate workstation, he is able to attach to server resources again, but for our customer, it's a useful obstacle for the average user.

Franz
