The owner can not only change permissions but can delete and write to a folder and subfolders that he is an owner of if that is a concern once he has granted himself the necessary permissions which can be full control. Having said that for trusted and competent users that may be perfectly fine in your situation. Anyone with write permissions or the user right to restore files and directories can restore files.

We use Windows Server 2003. Would it be advisable to grant trusted users the ownership permission on a network share? What implications would this have aside from the users being able to modify permissions? Does this have any impact on restoring files, etc?

We have users that are assigned the task of making sure that certain folders are "clean" and contain the contents that they are suppose to, and mgmt likes the idea of users being able to view the "owner" of the folders so that they can see who the "librarian" is, so that they can request changes to the folders that the librarian is in charge of.

Thanks,
Longer
