I was looking for an answer to a related question and found this thread.

I have a similar setup with a \home with individual user folders in it (eg \home\jsmith, etc).

I have set \home up as a share, but without individual shares for users.

This works well for PC's as their login script attaches directly to their personal folder.

However, we also have macs on our network. When they attach to \home, they see all of the folders (though if they click them, they disappear) and can only access their own. I would like them to just see their own folder. How do I do this?

In my current config, they have Read & Execute on the Home folder and Change and Read under Share permissions. On their personal folders, they have full control.

How do I make the other folders not show up? Is it a setting on those folders or on the home folder? Finally, since it's 100+ folders, is there an easy way to change it on all of them at once?

Thanks for any insights.
