Is there a "personal firewall" that does a good job of reporting / filtering incoming and outgoing connections that violate the firewall policy? A good solution might be simply letting me set up views of the firewall log so I can view it in different ways that suit my usage, in real time as well as historically.

After being away from the computer, I would like for example to see just the failed incoming connections. I would like to be able to further filter things so that certain expected connection types I can ignore and not see in the log (e.g., port 137).

The tool gets brownie points if it can not only tell me about an incoming RPC, but can elaborate what RPC or DCOM service was requested.
