No. One account, one password.

Windows 2003 Service Pack 2 Enterprise edition is installed on my home PC.

I have granted a friend of mine to access my computer via remote desktop.

Today he had started flashget to download a file and just after that his internet connection failed, so the remote desktop session was disconnected (many hours passed since then and he is still offline PING!). A few minutes after he was disconnected, flashget found some more download mirrors and established about 50 TCP sessions rendering my internet connection very unstable for any new session attempt.

When his session is disconnected I cannot use remote control on it and my only option would be to logon to it. But when my friend is offline on the other side of the world and cannot unlock his session, my only option would be either to reset his password or to force logoff. I prefer not to do this.

Q:  
Is it possible to create two passwords for his account (one for him and one for me, which I can use to unlock his session if any problem happens again)?
