I got this working: 1) uncheck "Allow inheritable permissions from parent to propagate to this object." under Advanced and choosing to remove all permissions from that directory structure, 2) Add Full Control to Administrators.

But I am still mystified as to why the first approach did not work...

On my XP box, the local "users" group includes "authenticated users", which would, in turn, include administrators.

Using "deny" access is fraught with surprises – it is usually better to grant the required access and simply not grant access to those who are not to have it. Or, in your case, remove the specific accesses previously granted to "users".
