Hi, going through the security logs which I apparently don't do frequently enough, I found a computer account in AD that I don't recognize. I looked through my list and it wasn't on the list. Called the 1 vendor that gets in and it wasn't there's. The computer account's name is "Our Domain name" + "SEND" so: DOMAINSEND. I can't tell if it's a "real" computer or virtual. I can tell the account was created about a month ago and is being denied log on rights logging in as various legitimate users through Kerberos. I have done searches at Symantec, McAfee, Google, CNET, Microsoft and a few others with DOMAINSEND as the search criteria and got nothing back. My plan is to disable the computer account but wanted to see if anyone has come across anything similar. Kinda' scared to disable the account in case that action triggers something else. Any advice?

Never mind...I'm an idiot!
