Off the top of my head, perhaps you can reserve a "bad" IP address for the rogue system. I'm not sure if you can do this, but give it an IP address in a different subnet, that way it will not be able to communicate with any systems at all on your network. You can try experimenting with this on a test system. Let me know how you make out.

My servers are Server 2003, SP2. I have DHCP running well. I noticed a computer name in the Address list of the DHCP server that is not a computer that belongs to our company. All I have is the computer name and MAC address, which DHCP catches.

How can I block or prohibit this computer from getting an IP address or from using our network for whatever purpose??
