Hi.

I am having trouble about how to configure the ntfs permissions on a workgroup based file system.

I have a huge file archive on an accounting office full of office documents on different user.

I created usernames for each user on workgroup and I moved whole documents to the server.

I want to apply user based security over ntfs permissions on user names.

I already moved whole documents to a folder called "documents" and every user's documents is under its name folder.

"d:\Documents\"username"\files.

this folder have all user permissions , I mean all users on the network can access the folder and files.

When I want to change the user permissions on those folders, it doesn't apply the changes to folders inside it. Even after I click apply these changes to folders under this folder. but it doesn't apply.

I want to create new folders with usernames and I want to give permissions on empty folders and then I want to move the recent documents into these new folders. how can I do it without changing user permissions which I did while I created?

thanks.

.
