if you want to control the trafic between domain clients and the domain controller, you can use the kerberos protocol instead of a port number on the firewall, kerberos is the protocol that moves the secured traffic between clients and the domain contoller.

"InputIO" wrote:

Hi guys,

i have more server on two different network layer separate across a firewall

..

Layer1 : All client

Layer2 : 2 Domain Controller

The question is :

wich port i need open on my firewall for permit the client to join a domain (only at setup) and after make possible a user domain authentication ?

Thanks in advance.
